Computing Infrastructures - System Dependability Reliability and Availability

The topics of the course: what are we going to see today?

HW Infrastructures:

System-level: Computing Infrastructures and Data Center Architectures, Rack/Structure;

Node-level: Server (computation, HW accelerators), Storage (Type, technology), Networking (architecture and technology);

Building-level: Cooling systems, power supply, failure recovery

SW Infrastructures:

Virtualization: Process/System VM, Virtualization Mechanisms (Hypervisor, Para/Full virtualization)

Computing Architectures: Cloud Computing (types, characteristics), Edge/Fog Computing, X-as-a service

Methods:

Reliability and availability of datacenters (**definition, fundamental laws**, RBDs)

Disk performance (Type, Performance, RAID)

Scalability and performance of datacenters (definitions, fundamental laws, queuing network theory)

What dependability is? (SLIDE Form the OVERVIEW SET)

- A measure of how much we trust a system...
...from a microwave oven up to an airplane and a large datacenter!
- The ability of a system to perform its functionality while exposing:

- **Reliability**

Continuity of
correct service

- **Availability**

Readiness for
correct service

- Maintainability

Ability for easy
maintainance

- Safety

Absence of
catastrophic
consequences

- Security

Confidentiality and
integrity of data

Reliability

The ability of a system or component to perform its required functions under stated conditions for a specified period of time
[IEEE610]

[IEEE610]: IEEE Standard Glossary of Software Engineering Terminology,
IEEE Std 610.12-1990 (R2002).

definition

Reliability

$R(t)$: probability that the system will operate correctly in a specified operating environment **until** time t

$$R(t) = P(\text{not failed during } [0, t])$$

assuming it was operating at time $t = 0$

- t is important!
- If a system needs to work for slots of ten hours at a time, then ten hours is the reliability target
- Often used to characterize systems in which even small periods of incorrect behavior are unacceptable (e.g. Impossibility to repair)

Characteristics

$1 - R(t)$: unreliability, also denoted $Q(t)$

$R(t)$ is a non-increasing function varying from 1 to 0 over $[0, +\infty)$

$$R(0) = 1$$

$$\lim_{t \rightarrow +\infty} R(t) = 0$$

$$f(x) = -\frac{dR(t)}{dt}$$

probability density function of the failure

Availability

The degree to which a system or component is operational and accessible when required for use [IEEE610]

- [IEEE610]: IEEE Standard Glossary of Software Engineering Terminology, IEEE Std 610.12-1990 (R2002).

$$\text{Availability} = \text{Uptime} / (\text{Uptime} + \text{Downtime})$$

- Fundamentally different from reliability
 - "reliability: does not break down ..."
 - "availability: even if it breaks down, it is working when needed..."
- Any examples of designs requiring high reliability/availability?

definition

Availability

$A(t)$: probability that the system will be operational at time t

$$A(t) = P(\text{not failed at time } t)$$

- Literally, readiness for service
- Admits the possibility of brief outages
- When the system is not repairable: $A(t) = R(t)$
- In general (repairable systems): $A(t) \geq R(t)$
- $1 - A(t)$: unavailability

Some numbers

Availability

Availability as a function of the "number of 9's"

Number of 9's	Availability	Downtime (mins/year)	Practical meaning
1	90%	52596.00	~5 weeks per year
2	99%	5259.60	~4 days per year
3	99.9%	525.96	~9 hours per year
4	99.99%	52.60	~1 hour per year
5	99.999%	5.26	~5 minutes per year
6	99.9999%	0.53	~30 secs per year
7	99.99999%	0.05	~3 secs per year

Some example

Number of 9's	Availability	Downtime/year	System
2	99%	~4 days	Generic web site
3	99.9%	~9 hours	Amazon.com
4	99.99%	~1 hour	Enterprise server
5	99.999%	~5 minutes	Telephone system
6	99.9999%	~30 seconds	Network switches

R(t) & A(t): Two points of view

Of course, they are related:

- if a system is unavailable it is not delivering the specified system services

It is possible to have systems with low reliability that must be available

- system failures can be repaired quickly and do not damage data, low reliability may not be a problem (for example a database management system)

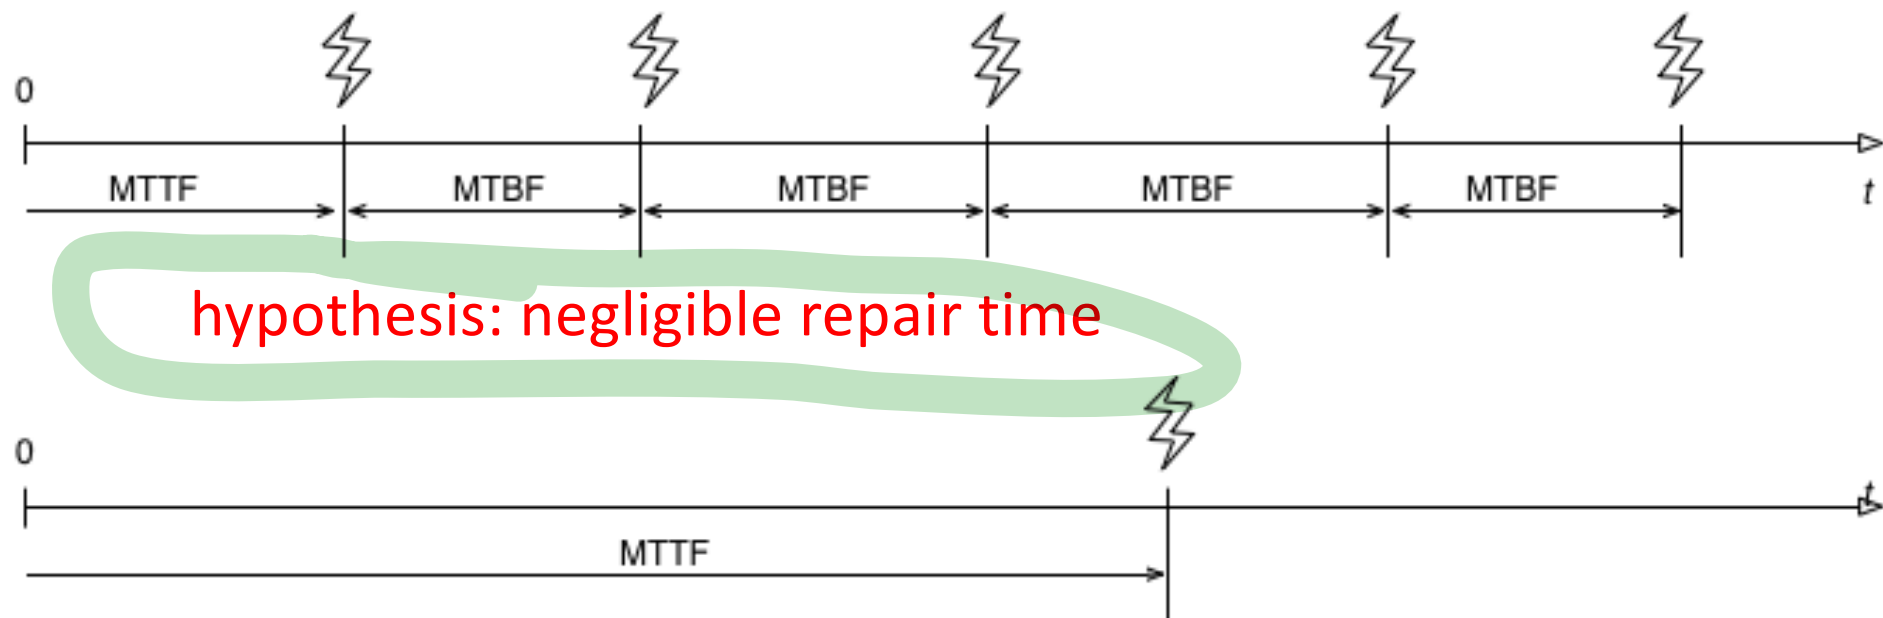

The opposite is generally more difficult...

R(t) & A(t) related indices

MTTF (Mean Time To Failure): mean time before *any* failure will occur

MTBF (Mean Time Between Failures): mean time between two failures

R(t) & A(t) related indices

MTTF (Mean Time To Failure): mean time before *any* failure will occur

R(t) & A(t) related indices

Other indices

MTTF: mean time to (first) failure, the up time before the first failure

MTBF: mean time between failures

$$\text{MTBF} = \frac{\text{total operating time}}{\text{number of failures}}$$

FIT: failures in time

- another way of reporting MTBF
- the number of expected failures per one billion hours (10^9) of operation for a device
- $\text{MTBF (in h)} = 10^9 / \text{FIT}$

$$\text{Failure Rate } \lambda = \frac{\text{number of failures}}{\text{total operating time}}$$

$$\text{MTBF} = \frac{1}{\lambda}$$

R(t) & A(t) related indices

Other indices

- **Infant Mortality:** failures showing up in new systems. Usually this category is present during the testing phases, and not during production phases.
- **Random Failures:** showing up randomly during the entire life of a system.
 - **Our main focus**
- **Wear Out:** at the end of its life, some components can cause the failure of a system. **Predictive maintenance** can reduce the number of this type of failures.

$R(t)$ & $A(t)$ related indices

Other indices

How to identify defective products and calculate MTTF?

Burn-in test: *stress* the system with excessive temperature, voltage, current, humidity so to accelerate wear out.

How to compute reliability?

Empirical Evaluation

- Let's consider n_0 independent and statistically identical elements deployed at time $t = 0$ in identical conditions $n(0) = n_0$
- At time t , $n(t)$ elements are not failed
- t_1, t_2, \dots, t_{n_0} are the times to failure of the n_0 elements
 - times to failure are independent occurrences of the random quantity τ

- Function $n(t) / n_0$ is the empirical function of reliability that as $n_0 \rightarrow \infty$ converges to the value: $n(t) / n_0 \rightarrow R(t)$

Different types of faults

- Hardware faults:
 - Electronic
 - Mechanical

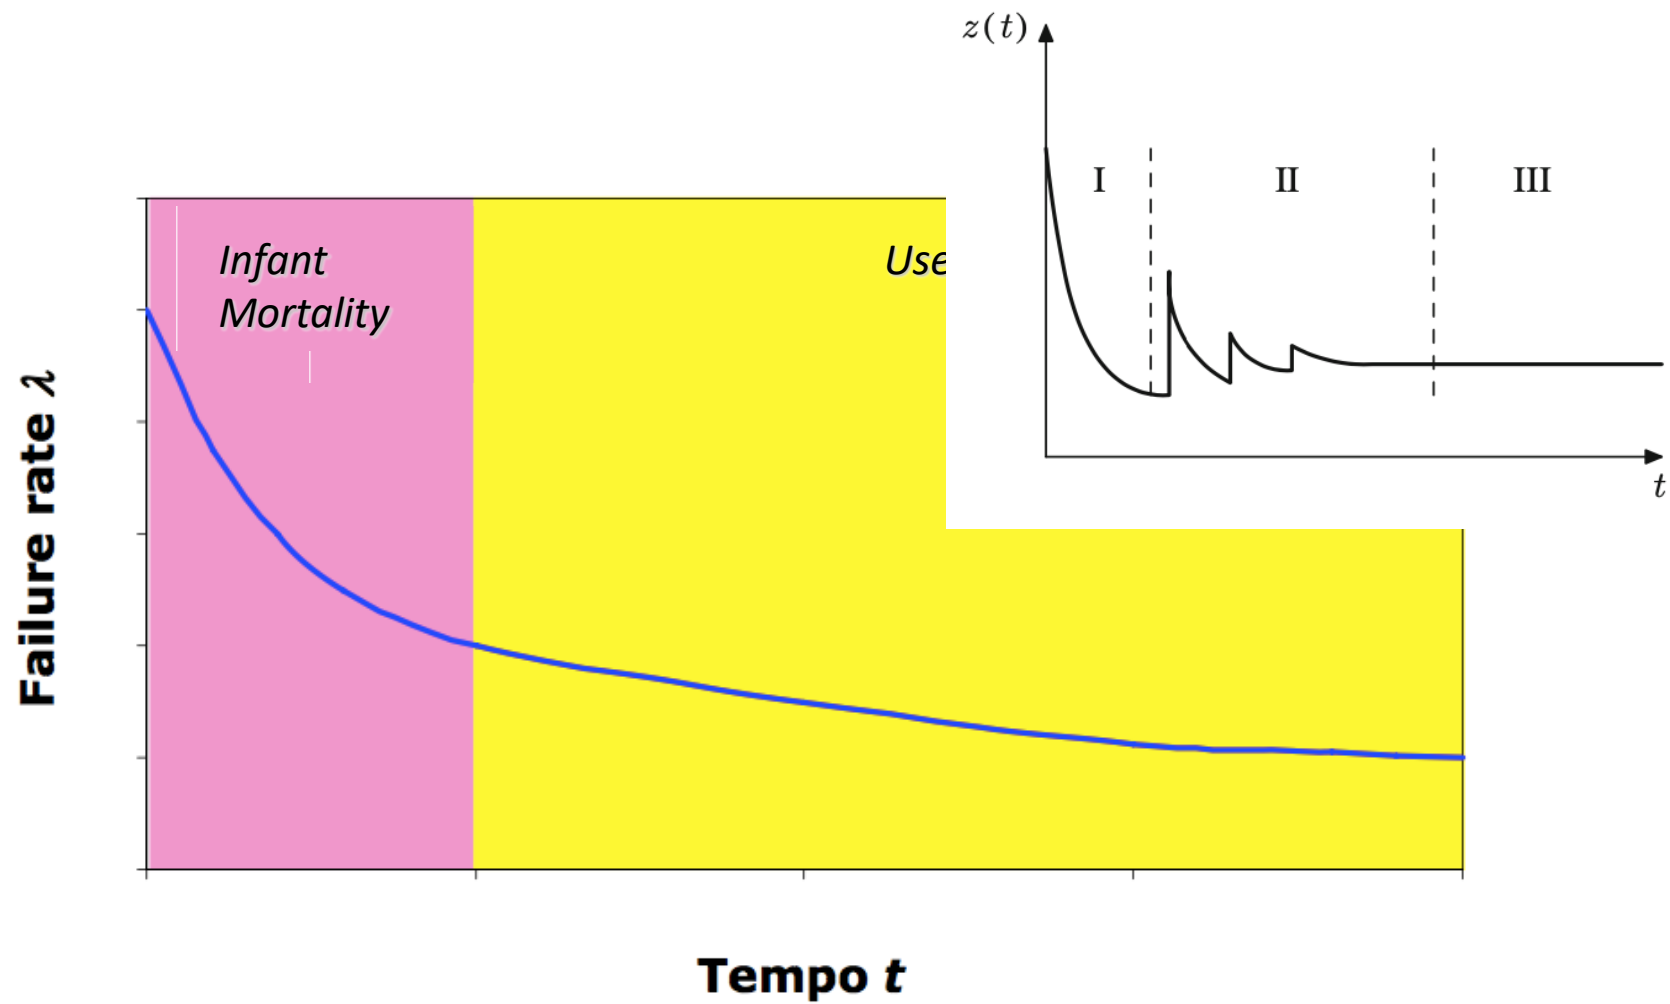

- Software faults:

Hardware: electronic components

R(t) ... what to do?

Exploitation of R(t) information is used to compute, for a complex system, its reliability in time, that is the expected lifetime

- computation of the MTTF

Computation of the overall reliability starting from the components' one

Within the course we consider only a reliability with an exponential distribution:

- Constant Failure rate

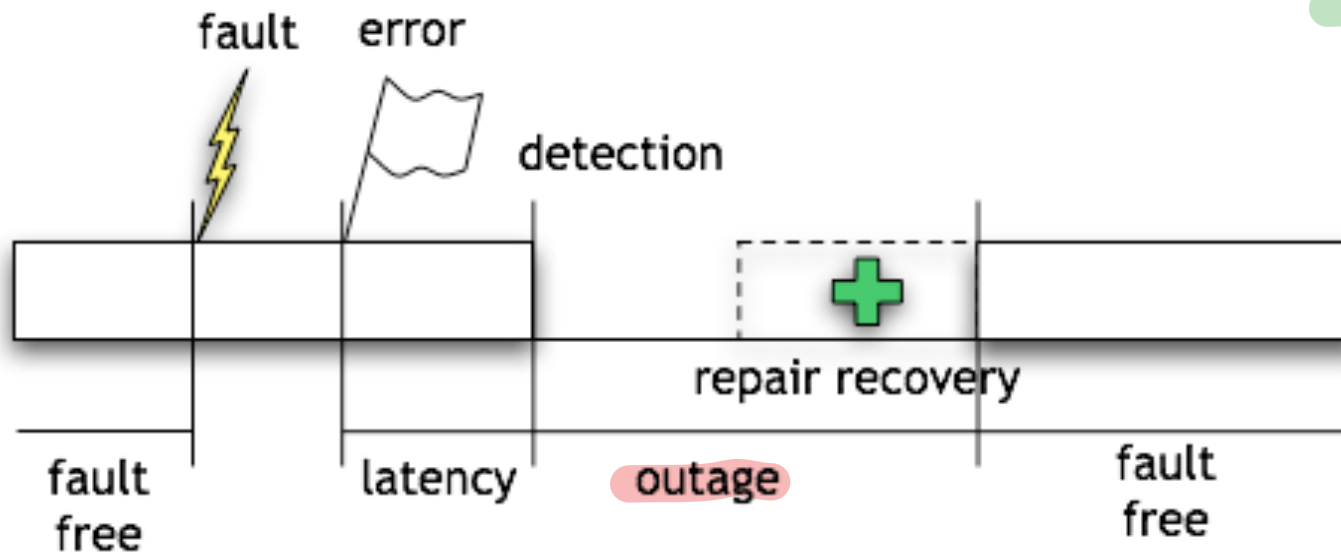

$$R(t) = e^{-\lambda t}$$

$$MTTF = \int_0^{\infty} R(t) dt = \frac{1}{\lambda}$$

Reliability terminology

Term	Description
Fault	A defect within the system
Error	A deviation from the required operation of the system or subsystem
Failure	The system fails to perform its required function

Reliability terminology

An example: a flying drone with an automatic radar-guided landing system

Fault: electromagnetic disturbances interfere with a radar measurement

Error: the radar-guided landing system calculates a wrong trajectory

Failure: the drone crashes to the ground

Reliability terminology

Another example: a tele-surgery system

Fault: radioactive ions make some memory cells change value (bitflip)

Error: some frames of the video stream are corrupted

Failure: the surgeon kills the patient

Reliability terminology

Not always the *fault – error – failure* chain closes

example: a tele-surgery system

Fault: radioactive ions make some memory cells change value (bitflip) but the corrupted memory does not involve the video stream

Error: no frames are corrupted

Failure: the surgeon carries out the procedure

Reliability terminology

Not always the *fault – error – failure* chain closes

example: a tele-surgery system

Fault: radioactive ions make some memory cells change value (bitflip) but the corrupted memory does not involve the video stream

Error: no frames are corrupted

Failure: the surgeon carries out the procedure

Non activated fault

Reliability terminology

Not always the *fault – error – failure* chain closes

example: a flying drone with automatic radar-guided landing

Fault: electromagnetic disturbances interfere with a radar measurement

Error: the radar-guided landing system calculates a wrong trajectory, but then, based on subsequent correct radar measurements it is able to recover the right trajectory

Failure: the drone safely lands

Reliability terminology

Not always the *fault – error – failure* chain closes

example: a flying drone with automatic radar-guided landing

Fault: electromagnetic disturbances interfere with a radar measurement

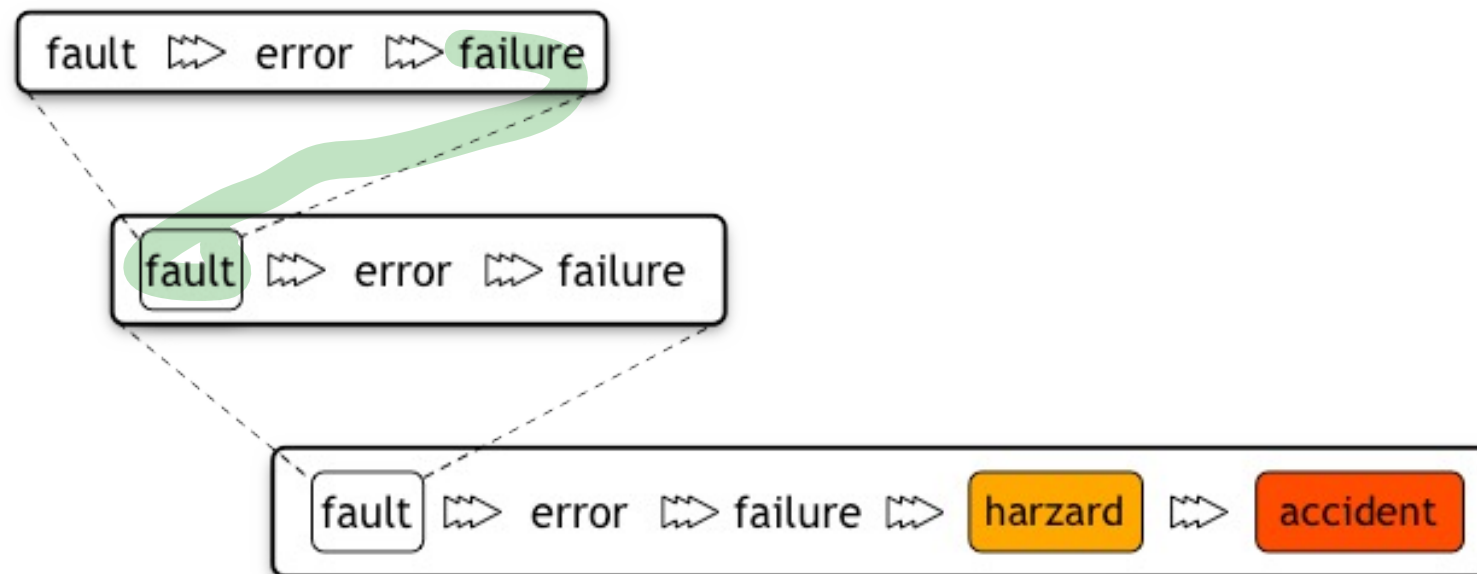

Error: the radar-guided landing system calculates a wrong trajectory, but then, based on subsequent correct radar measurements it is able to correct it

Failure: the drone safely lands

Non propagated
(or absorbed) error

Fault hierarchy

Fault-error-failure cascades can lead to life-threatening hazards
